Acknowledgement

The acreage, production, utilization, monthly and season price, and crop value statistics for Florida as shown in this summary and corresponding data for other citrus states are official estimates of the USDA's National Agricultural Statistics Service. Chilled and frozen pack statistics were compiled by the Florida Department of Citrus. Where data are from other sources, appropriate references appear. Records of the Division of Fruit and Vegetables, Florida Department of Agriculture and Consumer Services, were used in preparing production and utilization estimates. The Citrus Administrative Committee assisted in assembling these data. Many producers, shippers, processors, sales agencies, transportation firms, and others associated with the citrus industry voluntarily supplied basic data used to develop these statistics. Their contributions are sincerely appreciated.

The inventory data contained in this report were developed at the request of and with funds provided by Florida's Citrus Industry. Its leaders sought accurate information for projecting future production and recognized the requirement to maintain current citrus tree and acreage inventories. The work was directed by the Florida Agricultural Statistics Service which supervised photo interpretation, field checking, and assembly of the data. Field survey work is a continuing cooperative project of the Florida Agricultural Statistics Service and the Division of Plant Industry. Private and public officials contributed to this work by supplying information and other assistance.

Florida Citrus Pricing, Packout Rates and Sample Calculation of Grower's Return Prices

All prices reported in this publication, except the concentrate prices in the table on page eleven, are on-tree prices representing the average price received by growers for their fruit. The term "on-tree" relates to fruit returns to the grower after the costs of picking, hauling, and packing has been removed. Prices are based on records of commercial fresh fruit sales and processed fruit returns.

Each season, beginning with the first month that at least 3 percent of a fruit type is harvested, monthly estimates are computed. Reports from fresh fruit sales organizations and from packers provide data for an average freight-on board (f.o.b.) price. Processors report an average spot and cash price for fruit delivered to their plants. From these values, an estimated charge for picking, hauling, and packing is deducted to arrive at an on-tree price. The anticipated box utilization for the month is used to combine the fresh and processing price to obtain an average price for all methods of sales.

At the season's end, monthly price averages are computed and weighted by boxes utilized, to provide the preliminary season average price. A year later, after most processed products are sold, cooperatives and firms with participation plans report prices of fruit they handled. These prices, combined with the spot and cash prices collected earlier, are weighted together by varieties to determine the final processing price received by growers. From this price, charges for picking, hauling, and packing, as estimated by University of Florida economists, are deducted to arrive at the final on-tree price received by growers. The preliminary figures for the season are revised and released annually in late September.

Packout Rates

Fresh prices shown in this publication are for "pure fresh" or 100% packout. Grading diverts a portion of the crop from fresh use. Returns at processing plants for this diverted fruit will generally be less than for field run fruit because of extra costs. In order to compare fresh prices shown in this publication to the individual grower's return it is necessary to calculate a derived price for that crop. Below is an example and a blank table for calculating fresh returns based on packout rates.

The example describes a delivery of 1,000 boxes with a packout rate of 60% (0.60 in decimal format). At this rate, 600 boxes (1,000 x 0.60) are shipped fresh at a price of \$9.50 per 1 3/5 bushel box equivalent. The remaining 400 boxes (1,000 x 0.40) are eliminations hauled to a processing facility and receive a price of \$1.20. The grower receives \$5,700.00 for the fresh portion and \$480.00 for the processed portion. Dividing the total amount of \$6,180.00 by the total of 1,000 boxes results in a derived price of \$6.18 per box.

Sample Calculation of Grower's Return

	Packout Rate		Prorated Boxes	On-tree Price		Amount Received	Derived Price
	Percent	Decimal					
Shipped Fresh	60	0.60	600 x Fresh	\$9.50	=	\$5,700.00	
Eliminations	40	0.40	400 x Processed	\$1.20	=	\$480.00	
Delivered to Packinghouse	100	1.00	1,000			\$6,180.00	\$6.18

Calculate Your Return

	Packout Rate		Prorated Boxes	On-tree Price		Amount Received	Derived Price
	Percent	Decimal					
Shipped Fresh			x Fresh		=		
Eliminations			x Processed		=		
Delivered to Packinghouse							

2008-2009 Season Highlights

Production

Utilized citrus production for the 2008-2009 season in the United States totaled 12.0 million tons, down almost 7 percent from the 2007-2008 season's 12.8 million tons, and nearly 33 percent lower than the record high production of 17.8 million tons in 1997-1998. Florida accounted for 71 percent of the total, California produced 26 percent, and Texas and Arizona harvested the remaining 3 percent. Only Arizona, where fresh utilization was down but processed utilization nearly doubled, showed an increase with total production up 48 percent from 2007-2008. Both fresh and processed utilization were lower in the other states with total decreases of 6.6 percent in California, 7.2 percent in Florida, and 11 percent in Texas.

Production of Florida citrus in the 2008-2009 season was 189.1 million boxes. All categories of oranges, grapefruit, and specialty fruit showed decreases in production except the non-Valencia orange category. A significant contributing factor to the reduced production was lower average fruit per tree in all categories except non-Valencia oranges and Sunburst tangerines. Bearing trees were reduced from the previous season for all fruit types. Although the average size of Navel oranges was smaller this season, Valencia orange size was about the same as last season, while the average size of early-midseason oranges, grapefruit, tangelos, and tangerines was larger, requiring fewer pieces of fruit to fill a 1 3/5 bushel box.

The all orange crop production of 162.5 million boxes was down 4.6 percent. Production was 1.3 percent higher for non-Valencia oranges, but 10.3 percent lower for Valencia oranges. Final Navel production was 3.0 million boxes in 2008-2009, equal to the previous season's production. All grapefruit production of 21.7 million boxes was 18.4 percent less than the 2007-2008 season's production. Decreases in production were recorded for tangerines and tangelos. Honey tangerines had the largest decrease in production at over 55 percent.

Area and County Production

Total citrus production in 2008-2009 was down in all Florida commercial citrus production areas from the 2007-2008 season. The Indian River and Southern areas had decreases of 5.5 million and 5.1 million boxes. The Western area decrease of less than 1 million boxes was the smallest. The Central area led in total citrus production with 30 percent of all utilized fruit. Following were the Southern area with 26 percent and the Western area with 25 percent.

Nearly 89 percent of all oranges harvested came from the Central, Western, and Southern areas. Grapefruit production is concentrated in the Indian River area which produced 67 percent of the State's total. Together, the Central and Southern areas contributed 25 percent of the grapefruit crop. The Central area led with 32 percent of all oranges, 37 percent of all tangerines, and 33 percent of the tangelos. The Southern and Western areas each produced 28 percent of the oranges. The Southern area also contributed 26 percent of the tangerines. The Northern area produced 17 percent of the tangelos.

Production in the top four counties decreased by 5.6 percent. Together, they produced over 50 percent of all citrus. Polk led with 30.3 million boxes, Highlands moved into second with 23.2 million. Hendry dropped to third with 21.8 million boxes, and DeSoto completed the four with 20.6 million boxes. Losses were recorded in 25 counties with only Alachua, Hardee, Hillsborough, Marion, and Putnam producing more citrus.

Leading orange producers were Polk at 27.2 million boxes, Highlands at 22.1 million boxes, and Hendry at 20.5 million boxes. Desoto came in fourth again this season with nearly 20.3 million boxes. Combined, these four counties accounted for over 55 percent of the State's total oranges. With over 7 million boxes each, Indian River and St. Lucie far surpassed all other counties in grapefruit production. Together, they accounted for 66 percent of the State's grapefruit crop. Polk led in all tangerine production as well as the components (early tangerines and Honey tangerines). Lake, Highlands, Hendry, and Hardee completed the top five in all tangerine production. Polk County led in production of tangelos with almost 27 percent and Lake followed with about 13 percent. St. Lucie and Hendry came in third and fourth.

Estimates of county production are prepared from objective survey data used in forecasting citrus crop production. The apportionment of final harvest to the counties is based on bearing trees, an estimate of the average fruit per tree, and the drop and size surveys. Sample sizes used in these surveys and the distribution of the sample groves around the State are chosen to minimize error in the estimates of production. Estimates are not to be considered accurate for the counties as at the State or area levels.

Value

The preliminary value of the 2008-2009 United States citrus crop decreased 15 percent from last season, to \$2.74 billion (packinghouse-door equivalent). Total value of production for 2008-2009 was lower for all states and crops. Florida accounts for 55 percent of the total, California has 42 percent, and Arizona and Texas combine for the remaining 3 percent. Orange value of production decreased 11 percent, grapefruit value was down 14 percent, and tangelo value decreased 36 percent from the previous season. Tangerine and mandarin value of production was 11 percent lower than last season, and lemon value of production was down 35 percent. Beginning with the 2006-2007 season, Temple production and value were included in the non-Valencia component of Florida's orange estimates.

Florida's \$993.0 million (on-tree equivalent) preliminary value of the 2008-2009 citrus crop was 23 percent less than the 2007-2008 season's revised crop value of \$1.28 billion. The price per box was lower for all fruit types except the Honey tangerines and all tangerines. The total on-tree value was lower on all varieties. White grapefruit was down more than 50 percent from the previous season's revised value and the tangelo value dropped by more than 50 percent for the second consecutive season.

Preliminary value is based on that part of the crop priced at harvest, which accounts for all of the fresh fruit and about 40 percent of the processed. Nearly one-half of the processed oranges were priced but the figure for processed grapefruit and tangerines is about one-quarter of the total.

Citrus Value of Sales On-Tree-Florida: Crop Years 1999-2000 through 2008-2009

Crop year ¹	Value	Crop year ¹	Value
(1,000 dollars)	(1,000 dollars)	(1,000 dollars)	(1,000 dollars)
1999-2000	1,108,523	2004-2005	754,169
2000-2001	862,031	2005-2006	1,024,610
2001-2002	966,803	2006-2007	1,499,112
2002-2003	787,378	2007-2008 ²	1,283,994
2003-2004	891,500	2008-2009 ³	993,043

¹ Excludes lemons beginning in 2003-2004.

² Revised.

³ Preliminary.

Foreign Exports

Fresh fruit exports totaled 12.5 million 4/5 bushel cartons. Japan accounted for the majority of Florida grapefruit. Canada received the most of Florida's orange and specialty fresh fruit exports. More details are listed on page 45. A total of 9.65 million gallons of Frozen Concentrated Orange Juice (FCOJ), and 6.14 million gallons of Frozen Concentrated Grapefruit Juice (FCGJ) were exported in the 2008-2009 season.

Frozen Concentrate

Final Frozen Concentrated Orange Juice (FCOJ) yield, as reported by the Florida Department of Citrus, was 1.664452 gallons per box of 42° Brix concentrate, slightly below the record of 1.672737 set in the previous season. The early-midseason portion of the crop set a record at 1.597195 gallons per box. The previous early-midseason high was 1.584139 gallons per box which was attained in 1998-1999. The late crop yielded 1.750745 gallons per box following the record high 1.790343 gallons per box recorded in the previous season.

The final Frozen Concentrated Grapefruit Juice (FCGJ) yield was 1.273682 gallons per box of 40° Brix concentrate and lower than the 1.31020 gallons per box recorded in 2007-2008. The 1.364660 gallons per box in 2006-2007 is the FCGJ record. The final Frozen Concentrated Tangerine Juice (FCTJ) yield of 1.567257 gallons per box of 42° Brix concentrate is the highest recorded since the 1.677269 gallons per box in the 1999-2000 season. The 1.697333 gallons per box in 1998-1999 is the highest tangerine yield recorded.

Average Delivered-in Processed Price – Florida: Crop Year 2008-2009

Variety	Price per box	Price per pound of solids
	(dollars)	(dollars)
All oranges	8.038165	1.224619
Early-midseason	7.244725	1.156586
Valencia	8.582243	1.298077
All grapefruit	2.968603	0.622421
White	2.682537	0.585195
Colored	3.183944	0.648589

SOURCE: Florida Department of Citrus

Weather, by Months, Florida

In early January 2008, a cold snap dropped temperatures to the upper 20s and lower 30s across the citrus producing region. By the end of the month, warming temperatures brought daily highs up to the mid 70s. February had cool weather in the lower 30s. Light frost was reported on several mornings. In March, citrus growers enjoyed warming afternoons and beneficial rainfall. Early fertilizer applications were combined with irrigation to assist in tree growth and the fruit maturing process. Some growers hedged and topped trees after harvest to maintain a tree surface conducive to large size fruit for next season.

April temperatures were average, reaching the lower to mid 80s on most afternoons. No significant rainfall was reported after the first week of the month. Trees began to show slight afternoon wilt during the heat of the day. The bloom period finished during the first two weeks of the month, and the new fruit for next season formed quickly on the trees. May followed seasonal patterns, reaching the lower to mid 90s most days. Rainfall was not adequate enough to maintain tree vigor. Irrigation schedules continued at above normal rates.

Temperatures throughout the month of June reached the mid 90s regularly. Afternoon and evening rainfall was prevalent in all areas, assisting in fruit growth and helping trees with new foliage. During a few of the wettest periods, rainfall amounts were between 1½-2 inches in a single day. July temperatures remained near the normal mid 90s. Heavy rainfall during the entire month aided in fruit development. Excess amounts of rainfall were received when Tropical Storm Fay swept across the State twice during the month of August. Citrus producing counties along the East Coast had up to a foot of rain in a single week. Canals and lakes were mostly full and water was plentiful. Temperatures reached the lower 90s on most days. Most citrus areas looked good, with growers and owners positive about the new citrus season.

September brought cooler mornings, and generally drier conditions. Trees in tended groves had heavy foliage and healthy fruit. October and November brought cooler temperatures, but generally favorable weather for citrus. December temperatures were near normal, but rainfall was light. Regular irrigation prevented negative effects on the citrus crop.

January 2009 began with warm and dry conditions, with a cold snap in the third week bringing damaging temperatures to the citrus area. Cold fronts and freezing temperatures continued through February, as did the abnormally dry conditions. A gradual warming trend in early March brought seasonable temperatures, but severe drought conditions continued for most of the citrus producing region.

The drought conditions worsened in April, and were joined by very warm temperatures. Several days of strong showers and heavy, soaking rain in mid-May brought relief to the severe drought conditions. Temperatures also returned to average levels.

Temperatures and rainfall both returned to more seasonal patterns in June and July, with heavy rainfall in August aiding the citrus crop in fleshing out new growth. Heavy rains during the beginning of September and temperatures in the upper 80s made for conditions favorable to citrus growth. Drier conditions and seasonable temperature marked October and November. December saw an increase in rainfall, ending the moderate drought which had been in place. In the chart below, the 2008-2009 monthly rainfall is compared to the historical average data from ten stations scattered across the citrus producing area. The ten stations are: Apopka, Arcadia, Balm, Ft. Pierce, Immokalee, Clewiston, Lake Alfred, Sebring, Umatilla, and Kenansville.

History of Florida's Citrus Industry

Citrus is native to the Orient; it was carried westward by man, to India, the Mediterranean, and across the Atlantic. When Columbus landed on November 22, 1493, on his second voyage, he brought citrus seeds that were planted on Hispaniola. The first seeds planted on the mainland of the Americas were brought by the expedition of Juan de Grijalva when he landed in Central America between July 12 and July 20, 1518. The exact date of the introduction of citrus trees into Florida is not known, but from a statement made by Pedro Medendez, dated April 2, 1579, it appears that then citrus fruits were grown in abundance around St. Augustine. Early settlers in Florida some two centuries later found wild citrus trees scattered over the State. One of the oldest cultivated groves planted in Florida (Hume, 1926, p. 95) is thought to have been the Don Phillippe grove in Pinellas County, planted sometime between the years of 1809 and 1820. Nearly 1.5 million boxes were shipped in 1887-1888, the first season on record. Citrus production in Florida had reached a high of more than 5 million boxes when the Great Freeze of 1894-1895 nearly wiped out the entire citrus industry. It was not until 1909-1910 that this level was reached again. The highest production ever was reached in the 1997-1998 season, when Florida produced 304.5 million boxes.

¹ Fallglo and Sunburst varieties.

² Alachua, Citrus, Pinellas, and Putnam Counties.

Total citrus production in 2008-2009 was down in all Florida commercial citrus production areas from the 2007-2008 season. The Indian River and Southern areas were down the most with decreases of 5.5 million and 5.1 million boxes. The Western area decrease of less than 1 million boxes was the smallest.

Production in the top four counties decreased by 5.6 percent. Together, they produced over 50 percent of all citrus. Polk led with 30.3 million boxes, Highlands moved into second with 23.2 million. Hendry dropped to third with 21.8 million boxes, and DeSoto completed the four with 20.6 million boxes. Losses were recorded in 25 counties with only Alachua, Hardee, Hillsborough, Marion, and Putnam producing more citrus.

Leading orange producers were Polk at 27.2 million boxes, followed by Highlands at 22.1 million boxes, and Hendry at 20.5 million boxes. Desoto came in fourth again this season with nearly 20.3 million boxes. The four counties combined accounted for over 55 percent of the State's total oranges. Indian River and St. Lucie far surpassed all other counties in grapefruit production, with more than 14.3 million boxes combined. Together, they accounted for almost 2/3 of the State's grapefruit crop.

The Central area produced 37 percent of the State's tangerines and 33 percent of the tangelos. The Southern area produced the second highest specialty crop, including 26 percent of the tangerines. The Northern area came in third again accounting for 17 percent of specialty fruit.

Estimates of county production are prepared from objective survey data used in forecasting citrus crop production. The apportionment of final harvest to the counties is based on bearing trees, an estimate of the average fruit per tree, and the drop and size surveys. Sample size used in these surveys and the distribution of the sample groves around the State are chosen to minimize error in the estimates of production and are not to be considered as accurate for the counties as at the state or area levels.

Boxes of Fruit Per Tree

The Florida Agricultural Statistics Service conducts objective surveys to determine fruit per tree, average sizes, and droppage between August and maturity. These data are used to estimate production per tree for each type of citrus fruit, as shown in the following four tables. The estimates of production per tree are based on official end-of-season production estimates and the number of bearing trees indicated by the citrus tree inventory surveys. The averages of boxes per tree for age groups shown are calculated from estimates of fruit per tree in August, size at maturity, and drop between August and maturity. Additionally, the boxes are subdivided by production areas. Estimated boxes by types and age groups are weighted averages of the indicated seasons. Small sample sizes in some age/area cells and rounding may contribute to inconsistent averages.

World Citrus Production, by Selected Country: 2008-2009

Florida Public Land Survey System for Selected Citrus Producing Counties

Survey Procedures

This publication presents the results of the first annual survey of Florida citrus trees (following 22 biennial surveys) and is the third using digital imagery. The remotely sensed data allows for rapid replacement and maintenance of background images. Grove boundaries are digitized and saved as geodatabases in our GIS. The software provides additional tools to enhance comparative photo interpretation for grove change detection. Field checking of new and altered acreage follows. Changes detected on images and in field observations are used to update the previous inventory. This technology provides current tree inventory data for evaluating Florida's potential citrus production in a shorter period of time and at less cost than by ground survey methods alone.

The data in this report relate to commercial groves, those containing a minimum of 50 trees from which fruit is generally sold. In addition, the grove must have been cultivated and trees must show viable growth in the limb scaffold. Variety totals were rounded to the nearest acre and one hundred trees. All item totals that fell below these parameters were listed as zero. For this reason, users are cautioned that zero cells in the data tables could actually have a positive entry, but would be less than one half acre and below 50 trees.

The acreage shown is land which is actually planted with citrus trees. Bayheads, ponds, sinkholes, drainage canals, lateral and swale ditches, roads, turn rows, and wide middles were excluded. Where vacancies within a commercial grove were numerous, they were counted and acreage was then reduced to equivalent net acres of commercial trees. Non-bearing trees are listed by the calendar year in which set. Bearing trees are aggregated into three year groupings (except for the three oldest age groupings). When available, grove managers' records were used to establish age. Young tree age was estimated from both trunk circumference and tree height.

Identification of citrus varieties is generally dependent upon the presence of fruit. Many young groves visited for the first time are indexed as unidentified until fruit is available for variety determination. Acreage and trees in this report listed as "Unidentified" will be resurveyed and classified by variety in the next inventory. The unidentified trees and acres are listed by year set and by county under all Florida citrus. The unidentified trees and acres are also included in the all orange and all grapefruit totals.

Data itemized under "Other citrus" include minor types and varieties, such as K-Early Citrus, kumquats, limes, Ortaniques, Ponkans, pummelos, certain tangerines (Dancy, Robinson, and Satsuma), unclassified citrus, and unidentified mandarins. They are not reported individually or by year set within county due to lack of space.

The Florida Agricultural Statistics Service first began indexing citrus groves on aerial photography with the January 1966 survey. The 1966 inventory report included detailed data by county, variety, and year set; and the survey was designed for quick and economical updating. Subsequent surveys, using aerial photography, were conducted as of January every two years through 2006. Imagery covering every county has been acquired. Survey personnel received field kits containing a plot map of the digital imagery covering one quadrant of a township (9 sq. mi.) and printouts to assist in locating groves needing inspection.

On the computer, digital imagery layers can be turned on and off while working in a county file permitting comparison between different time periods. Photo interpreters identify all groves where new trees appear. These groves are then visited by ground crews. If field inspection finds a significant number of new trees, a count is made and the older trees or vacancies reduced accordingly. Based on this new count of trees, the acreage is recalculated for each record in the grove.

With the change to an annual survey came a systematic division of the workload. Florida land is divided into townships composed of 36 sections, each usually 1 square mile in area. In an odd-numbered year, those sections in the northern half of each township are visited. The sections in the southern half of the townships are visited during the even-numbered years. As time permits, additional grove inspections are performed during the survey period.

Field personnel identify varieties in blocks where trees were too young to be identified in earlier surveys, change the status of declining blocks, delineate new groves, and record new trees in existing groves. In blocks of citrus which are interset, acreage is proportionate to the number of trees of each variety or age in the block. In the multi-reset blocks, two or more resets are planted for each tree removed and the spacing must be averaged due to the variable distance between trees. The spacing between rows in one direction remains constant for grove travel. Field work is completed in mid-July.

Following field inspection, photo interpreters create polygons which are linked to datasets, and saved in county geodatabases for all new citrus groves. Changes in variety blocks may result in alterations to grove boundaries or status. A software tool provides the means to measure the exact acreage of new and altered citrus groves. All statistical information (identifying features, variety, year set, tree spacing, tree numbers, and vacancies) is then keyed into a database and retained for future use. Net acres are computed from the combination of tree numbers and tree spacings as measured by field personnel.

New maps are plotted and new section tabulations are printed to prepare updated field kits since resurveying is a continual process. Quality checks for accurate variety counts will be conducted as well as the identification of the three year old plantings that are to be included in next year's objective count surveys.

During the major portion of the survey, the Division of Plant Industry supplied trained citrus technologists with 4-wheel drive vehicles to work in conjunction with the tree inventory field inspection team.

Survey Highlights

Results of the annual commercial citrus inventory show a decrease of 7,763 acres, or a net change of -1.3 percent. The downward trend lost momentum as new trees were made available to citrus owners and approximately 12,155 acres of new plantings occurred in this one year period, well above the averages of the 2006 and 2008. The elimination of diseased trees contributed to the gross loss of 19,918 acres.

Since the year 2000, total acreage has declined nearly 32% or the equivalent of 263,461 acres. The drop of more than 8% of citrus trees since the 2006 tree inventory is a result of increased tree removals. In combination with the latest commercial citrus tree inventory, abandoned citrus acreage was identified. Results of this inventory indicated a 6.5% increase in abandoned acreage.

Of the 30 counties included in the annual citrus inventory, 17 recorded decreases and 13 showed increases in acreage. Martin County experienced the greatest loss in acreage at 4,170, while Brevard County had the highest percentage loss at 18.6. Hardee and Polk had the largest gains and Polk continues to lead with the most acres at 82,629. Hendry is second with 62,000 acres while Highlands and DeSoto follow with over 62,000 acres each. For total trees, Hendry remains the leader with 10 million, followed by Polk with 9.8 million, DeSoto with 8.3 million, and Highlands with 8.0 million trees.

Total citrus trees are down almost 2.0 percent from 75,376,100 in 2008 to 74,090,500 in 2009. Of the total, oranges comprise 88 percent, grapefruit 8 percent and the remainder includes specialty and other citrus at 4 percent. Since 2008, bearing trees decreased 2.06 percent to 69,565,700 while nonbearing trees increased 3.4 percent to 4,524,800.
