Acknowledgement

The acreage, production, utilization, monthly and season price, and crop value statistics for Florida as shown in this summary and corresponding data for other citrus states are official estimates of the USDA's National Agricultural Statistics Service. Chilled and frozen pack statistics were compiled by the Florida Department of Citrus. Appropriate references appear when data are from other sources. Records of the Division of Fruit and Vegetables, Florida Department of Agriculture and Consumer Services, were used in preparing production and utilization estimates. The Citrus Administrative Committee assisted in assembling these data. Many producers, shippers, processors, sales agencies, transportation firms, and others associated with the citrus industry voluntarily supplied basic data used to develop these statistics. Their contributions are sincerely appreciated.

The inventory data contained in this report were developed at the request of and with funds provided by Florida's citrus industry. Its leaders sought accurate information for projecting future production and recognized the requirement to maintain current citrus tree and acreage inventories. The work was directed by the Florida Agricultural Statistics Service which supervised photo interpretation, field checking, and assembly of the data. Field survey work is a continuing cooperative project of the Florida Agricultural Statistics Service and the Division of Plant Industry. Private and public officials contributed to this work by supplying information and other assistance.

Statistical Methodology

Survey Procedures: Grower, packer, and objective measurement surveys are used to collect acreage, production, yield, price, and value data. Grower and packer surveys are conducted by mail, telephone, and personal interview. Objective measurement data is collected in citrus groves.

Estimating Procedures: Information obtained from the citrus grower, packer, and objective measurement surveys along with administrative data is used to establish estimates of bearing acres, production, yield, price, and value. These estimates are reviewed for errors, reasonableness, and consistency with historical estimates.

Revision Policy: Current season estimates are open for revision in April and August.

Reliability: The citrus grower and packer surveys are subject to non-sampling errors such as omission, duplication, and mistakes in reporting, recording, and processing the data. These errors cannot be measured directly, but are minimized through rigid quality controls in the data collection process and a careful review of all reported data for consistency and reasonableness.

Terms and Definitions

Box: 1-3/5 bushel equivalent. See page 11 for a table of citrus box weights by fruit type and state. One box equals 2 cartons.

Brix: A measure of the concentration of soluble solids in juice, mostly sugar content as well as salts, protein, and acid content. It is a quality factor that helps determine when the fruit is ready for harvest.

Citrus crop year: Begins with the bloom of the first year listed and ends with the year harvest is completed.

Equivalent on-tree (EOT) price: Represents the PHD price minus picking and hauling costs.

Freight on board (FOB) price: A commercial price term that signifies a contractual agreement between a buyer and a seller to have the subject of a sale delivered to a designated place, usually either the "place of shipment" or the "place of destination," without expense to the buyer. This term indicates delivery will be made on board or into a carrier by the shipper without charge. The abbreviation FOB is usually followed by a shipping point or destination. Reports from fresh fruit sales organizations and from citrus packers provide data for an average FOB price.

Packinghouse door (PHD) price: The packinghouse door is generally referred to as the point of first sale. PHD prices are calculated by subtracting costs incurred through the packinghouse from the FOB price. These costs may include sorting, grading, packing, cooling, etc.

Marketing Districts: See map on page 104. Florida Statutes 601.091 states:

(2) The "Indian River" production area of this state shall encompass only that part of the state particularly described as follows: Beginning at a point on the shore of the Atlantic Ocean where the line between Flagler and Volusia Counties intersects said shore, thence follow the line between said two counties to the southwest corner of Section 23, Township 14 South, Range 31 East; thence continue south to the southwest corner of Section 35, Township 14 South, Range 31 East; thence east to the northwest corner of Township 15 South, Range 32 East; thence south to the southwest corner of Township 17 South, Range 32 East; thence east to the northwest corner of Township 18 South, Range 33 East; thence south to the St. Johns River, thence along the main channel of the St. Johns River and through Lake Harney, Lake Poinsett, Lake Winder, Lake Washington, Sawgrass Lake, and Lake Helen Blazes to the range line between Ranges 35 East and 36 East; thence south to the south line of Brevard County; thence east to the line between Ranges 36 East and 37 East; thence south to the southwest corner of St. Lucie County; thence east to the line between Ranges 39 East and 40 East; thence south to the south line of Martin County; thence east to the line between Ranges 40 East and 41 East; thence south to the West Palm Beach Canal (also known as the Okeechobee Canal); thence follow said canal eastward to the mouth thereof; thence east to the shore of the Atlantic Ocean; thence northerly along the shore of the Atlantic Ocean to the point of beginning.

(3) The "Gulf" production area of this state shall encompass all of Charlotte, Collier, Glades, Hendry, and Lee Counties.

(4) The "Florida SunRidge" production area of this state shall encompass all the area of the state not included within the boundaries established by subsections (2) and (3).

Florida Citrus Pricing

All prices reported in this publication, except the prices in the table on page 11, are on-tree prices representing the average price received by growers for their fruit. The term "on-tree" relates to fruit returns to the grower after the costs of picking, hauling, and packing has been removed. Prices are based on records of commercial fresh fruit sales and processed fruit returns.

Each season, beginning with the first month that at least 3 percent of a fruit type is harvested, monthly estimates are computed. Reports from fresh fruit sales organizations and from packers provide data for an average freight-on board (FOB) price. Processors report an average spot and cash price for fruit delivered to their plants. From these values, an estimated charge for picking, hauling, and packing is deducted to arrive at an on-tree price. The anticipated box utilization for the month is used to combine the fresh and processing price to obtain an average price for all methods of sales.

At the season's end, monthly price averages are computed and weighted by boxes utilized to provide the preliminary season average price. A year later, after most processed products are sold, cooperatives and firms with participation plans report prices of fruit they handled. These prices, combined with the spot and cash prices collected earlier, are weighted together by varieties to determine the final processing price received by growers. From this price, charges for picking, hauling, and packing, as estimated by University of Florida economists, are deducted to arrive at the final on-tree price received by growers. The preliminary figures for the season are revised and released annually in late September.

Packout Rates

Fresh prices shown in this publication are for "pure fresh" or 100% packout. Grading diverts a portion of the crop from fresh use. Returns at processing plants for this diverted fruit will generally be less than for field run fruit because of extra costs. In order to compare fresh prices shown in this publication to the individual grower's return it is necessary to calculate a derived price for that crop. Below is an example and a blank table for calculating fresh returns based on packout rates.

The example describes a delivery of 1,000 boxes with a packout rate of 60% (0.60 in decimal format). At this rate, 600 boxes (1,000 x 0.60) are shipped fresh at a price of \$9.50 per 1 3/5 bushel box equivalent. The remaining 400 boxes (1,000 x 0.40) are eliminations hauled to a processing facility and receive a price of \$1.20. The grower receives \$5,700.00 for the fresh portion and \$480.00 for the processed portion. Dividing the total amount of \$6,180.00, by the total of 1,000 boxes, results in a derived price of \$6.18 per box.

Sample Calculation of Grower's Return

	Packout Rate		Prorated Boxes	On-tree Price		Amount Received	Derived Price
	Percent	Decimal					
Shipped Fresh	60	0.60	600 x Fresh	\$9.50	=	\$5,700.00	
Eliminations	40	0.40	400 x Processed	\$1.20	=	\$480.00	
Delivered to Packinghouse	100	1.00	1,000			\$6,180.00	\$6.18

Calculate Your Return

	Packout Rate		Prorated Boxes	On-tree Price		Amount Received	Derived Price
	Percent	Decimal					
Shipped Fresh			x Fresh		=		
Eliminations			x Processed		=		
Delivered to Packinghouse							

FLORIDA CITRUS HARVESTING SEASON

2010-2011 Season Highlights

Production

Florida accounted for 63 percent of the total U.S. citrus production with 165.9 million boxes of citrus in the 2010-2011 season, up 4 percent from the previous season's revised 159.4 million boxes. Production increases were noted for all varieties except white and colored grapefruit and the late maturing Honey tangerines.

All orange production increased 5 percent to 140.3 million boxes. Navel production is 2.65 million boxes, up 15 percent from last season. All grapefruit production is down 3 percent to 19.8 million boxes. Honey tangerine production is down 7 percent from the previous season but offset by a 16 percent increase in early tangerines, resulting in a 4 percent increase in all tangerines.

The \$1.145 billion preliminary value of the 2010-2011 citrus crop is 2 percent greater than the revised value of \$1.118 billion for 2009-2010. The price per box is higher for non-Valencia oranges, tangelos, and Honey tangerines. The tangelo on-tree value increased 58 percent from last season. Only the grapefruit on-tree values are lower.

Area and County Production

Total citrus production in 2010-2011 was up in the Central and Southern areas but down in Indian River, Northern, and the Western areas from the 2009-2010 season. The Northern and Western areas were down the most with decreases of 968 thousand and 915 thousand boxes respectively. Indian River production of grapefruit was unchanged and losses in late season Valencia oranges were nearly offset by increases in the early and midseason orange varieties. The top 5 citrus producing counties were Polk (29.8 million), Highlands (23.1 million), Hendry (19.3 million), DeSoto (17.5 million), and Hardee (12.8 million). The greatest losses of production occurred in Martin and DeSoto Counties.

Estimates of county production are prepared from objective survey data used in forecasting citrus crop production. The apportionment of final harvest to the counties is based on bearing trees, an estimate of the average fruit per tree, and the drop and size surveys. Sample size used in these surveys and the distribution of the sample groves around the State are chosen to minimize error in the estimates of production and are not to be considered as accurate for the counties as at the State or area levels.

Value

The value of the 2010-2011 United States citrus crop increased slightly from last season, to \$2.98 billion (packinghouse-door equivalent). Orange value of production decreased 1 percent from last season and grapefruit value is down 6 percent. Tangerine and mandarin value of production is 15 percent higher than last season and lemon value of production is up 1 percent. Tangelo value increased 48 percent from the previous season.

Florida's \$1.145 billion preliminary on-tree value of the 2010-2011 citrus crop is 2 percent greater than the revised value of \$1.118 billion for 2009-2010. The price per box is higher for non-Valencia oranges, tangelos, and Honey tangerines. The tangelo on-tree value increased 58 percent from last season. Only the grapefruit on-tree values are lower.

Foreign Exports

Fresh fruit exports totaled 11.2 million 4/5 bushel cartons. Japan accounted for the majority of Florida grapefruit exports. Canada received most of Florida's orange and specialty fresh fruit exports. More details are listed on page 45. A total of 28.5 million gallons of Frozen Concentrated Orange Juice (FCOJ), and 5.8 million gallons of Frozen Concentrated Grapefruit Juice (FCGJ) were exported in the 2010-2011 season.

Citrus Value of Sales On-Tree-Florida: Crop Years 2001-2002 through 2010-2011

Crop year	Value ¹	Crop year	Value ¹
	(1,000 dollars)		(1,000 dollars)
2001-2002	966,803	2006-2007	1,499,112
2002-2003	787,378	2007-2008	1,283,994
2003-2004	891,500	2008-2009	1,046,735
2004-2005	754,169	2009-2010 ²	1,118,343
2005-2006	1,024,610	2010-2011 ³	1,145,065

¹ Excludes lemons beginning in 2003-2004.

² Revised.

³ Preliminary.

Frozen Concentrate

Final Frozen Concentrated Orange Juice (FCOJ) yield, as reported by the Florida Department of Citrus, was 1.586081 gallons per box of 42° Brix concentrate, far below the record of 1.672737 set in the 2007-2008 season. The early-midseason portion of the crop finalized at 1.522652 gallons per box. The late crop yielded 1.664737 gallons per box.

The final Frozen Concentrated Grapefruit Juice (FCGJ) yield was 1.327872 gallons per box of 40° Brix concentrate.

The final Frozen Concentrated Tangerine Juice (FCTJ) yield of 1.528083 gallons per box of 42° Brix concentrate was higher than last season's final of 1.438629 gallons per box.

Average Delivered-in Processed Price – Florida: Crop Year 2010-2011

[Price for fruit used in concentrate by variety]

Variety	Price per box	Price per pound of solids
	(dollars)	(dollars)
All oranges	9.208375	1.461369
Early-midseason	8.218270	1.370029
Valencia	10.181235	1.542958
All grapefruit	6.189697	1.271174
White	5.786110	1.240730
Colored	6.593248	1.299146

AZ	(X)	⁵ (X)	² 80	⁴ 80	(X)

X Not applicable.

¹ Includes Temples and tangelos at 90 pounds.

² Was 75 pounds prior to the 2010-2011 season.

³ Was 67 pounds from 1993-1994 to 2009-2010 and 65 pounds prior to the 1993-1994 season.

⁴ Was 76 pounds prior to the 2010-2011 season.

⁵ Was 67 pounds from 1993-1994 to 2008-2009 and 64 pounds prior to the 1993-1994 season.

Weather, by Months-Florida: Crop Year 2010-2011

January 2010 began with cold temperatures across the citrus region. There were ten nights of very low temperatures, leading to increased harvesting. Mild drought conditions initially existed, but were eliminated by the end of the month. Despite a few cold nights, February was generally mild, and the citrus region was drought free.

March began with mild temperatures. Heavy, soaking rains covered the state during the early stages of the bloom, helping to keep the state drought free. April and May saw seasonable temperatures and sufficient rainfall to maintain the drought free conditions. A number of areas experienced localized flooding, prompting some growers to pump excess water out of the groves into canals and reservoirs. By the end of the month, the heavy showers tapered off. Typical Florida summer weather patterns returned with quick-moving late afternoon and evening rain showers following days full of sunshine.

June and July both exhibited normal Florida weather patterns, consisting of warm days into the mid to upper 90s with afternoon thunderstorms and showers most days. Rainfall, while locally heavy, was primarily isolated to Western and Southern counties, allowing mild drought conditions to arise in the Indian River Area and along the East Coast. Heavy, but scattered showers and typical summer temperatures continued through August in some areas, while drought conditions in Indian River and surrounding counties worsened to moderate. Lighter showers and normal temperatures in September across the citrus region contributed to the continued worsening of the drought conditions to severe.

October and November saw mild temperatures and even drier conditions, as drought conditions, which were found across most of the citrus area, worsened to moderate in some areas, and extreme in others. The entire citrus producing region was in various stages of drought. December's dry conditions perpetuated the drought, while two major cold fronts brought temperatures down into the teens and twenties in some places. The first half of January 2011 brought a slight worsening of the drought, while rainfall during the last couple of weeks brought a lessening of the drought to many counties.

Normal temperatures and sparse rain marked the complete month of February. Heavy rains during the last half of March brought relief in the western portion of the citrus region, but extreme drought conditions persisted in the eastern portion. Drought conditions continued thru June, with heavier, but scattered rains lessening the drought to isolated areas by mid-July into August.

In the chart below, the 2010-2011 monthly rainfall is compared to the historical average data from 10 stations scattered across the citrus producing area. The 10 stations are: Apopka, Arcadia, Balm, Clewiston, Ft. Pierce, Immokalee, Kenansville, Lake Alfred, Sebring, and Umatilla.

¹ Average weighted by bearing trees.

The Florida Agricultural Statistics Service conducts objective surveys to determine fruit per tree, average sizes, and dropage between August and maturity. These data are used to estimate production per tree for each of four types of citrus fruit, as shown in the following tables. The estimates of production per tree are based on official end-of-season production estimates and the number of bearing trees indicated by the Commercial Citrus Inventory. The averages of boxes per tree for age groups shown are calculated from estimates of fruit per tree in August, size at maturity, and drop between August and maturity. Additionally, the boxes are subdivided by production areas. Estimated boxes by types and age groups are weighted averages of the indicated seasons. Small sample sizes in some age/area cells and rounding may contribute to inconsistent averages.

Citrus Production, by Type by Selected Country: 2010-2011

Florida Public Land Survey System for Selected Citrus Producing Counties

Survey Procedures

This publication presents the results of the third annual survey of Florida citrus trees (following 22 biennial surveys) and is the fifth using digital imagery. The Florida Agricultural Statistics Service first began indexing citrus groves on aerial photography with the January 1966 survey. The 1966 inventory report included detailed data by county, variety, and year set and the survey was designed for quick and economical updating. Subsequent surveys, using aerial photography, were conducted as of January every two years through 2006. The remotely sensed data now used allows for rapid replacement and maintenance of background images. Grove boundaries are digitized and saved as geodatabases in our Geographic Information System (GIS). GIS software provides tools to enhance comparative photo interpretation for grove change detection. This technology provides current tree inventory data for evaluating Florida's potential citrus production in a shorter period of time and at less cost than by ground survey methods alone.

With the change to an annual survey came a systematic division of the workload. Florida land is divided into townships composed of 36 sections, each usually 1 square mile in area. In seasons ending in odd-numbered years, those sections in the northern half of each township are visited. The sections in the southern half of the townships are visited during the even-numbered years. As time permits, additional grove inspections are performed during the current survey period. Field work is completed in mid-July of each year.

Field personnel identify varieties in blocks where trees were too young to be identified in earlier surveys, change the status of declining blocks, delineate new groves, and record new trees in existing groves. In blocks of citrus which are interset, acreage is proportionate to the number of trees of each variety or age in the block. In the multi-reset blocks, two or more resets are planted for each tree removed and the spacing must be averaged due to the variable distance between trees. The spacing between rows in one direction remains constant for grove travel.

After field inspection, photo interpreters create polygons which are linked to datasets, and saved in county geodatabases for all new citrus groves. Changes in variety blocks may result in alterations to grove boundaries or status. A software tool provides the means to measure the exact acreage of new and altered citrus groves. All statistical information (identifying features, variety, year set, tree spacing, tree numbers, and vacancies) is then keyed into a database and retained for future use. Net acres are computed from the combination of tree numbers and tree spacing as measured by field personnel.

Throughout the survey, new maps are plotted and new section tabulations are printed to prepare updated field kits since resurveying is a continual process. Quality checks for accurate variety counts will be conducted as well as the identification of the three-year-old plantings that are to be included in next year's objective count surveys.

The data in this report relate to commercial groves, those containing a minimum of 50 trees from which fruit is generally sold. In addition, the grove must have been cultivated and trees must show viable growth in the limb scaffold. Variety totals were rounded to the nearest acre and one hundred trees. Item totals that fell below these parameters were listed as zero. For this reason, users are cautioned that zero cells in some of the data tables could actually have a positive entry, but would be less than one half acre and below 50 trees.

The acreage shown is land which is actually planted with citrus trees. Bayheads, ponds, sinkholes, drainage canals, lateral and swale ditches, roads, turn rows, and wide middles were excluded. Where vacancies within a commercial grove were numerous, they were counted and acreage was then reduced to equivalent net acres of commercial trees. Non-bearing trees are listed by the calendar year in which set. Bearing trees are aggregated into three year groupings (except for the three oldest age groupings). When available, grove managers' records were used to establish age. Young tree age was estimated from both trunk circumference and tree height.

Identification of citrus varieties is generally dependent upon the presence of fruit. Many young groves visited for the first time are indexed as unidentified until fruit is available for variety determination. Acreage and trees in this report listed as "Unidentified" will be resurveyed and classified by variety in the next inventory. The unidentified trees and acres are listed by year set and by county under all Florida citrus. The unidentified trees and acres are also included in the all orange and all grapefruit totals.

Data itemized under "Other citrus" include minor types and varieties, such as K-Early Citrus, kumquats, limes, Ortaniques, Ponkans, pummelos, certain tangerines (Dancy, Robinson, and Satsuma), unclassified citrus, and unidentified mandarins. They are not reported individually or by year set within county.

Survey Highlights

Results of the annual commercial citrus inventory show total citrus acreage is 541,328, down over 2 percent, from the last survey. Compared to the previous inventory, the net decrease of 12,709 acres is less with a lower gross loss (21,769) and fewer new plantings (9,060).

Of the 30 counties included in the survey, 23 recorded decreases in acreage, 5 showed increases, and 2 are unchanged. Martin County, down 4,567 acres, has suffered the greatest loss for three straight years and has been declining since 1994. Desoto County has recorded gains in the last 4 surveys and this year's gain of 739 is the most of any county. Polk remains the leader in acreage with 82,577 and has taken the lead in trees with 9.9 million.

Orange acreage declined for the seventh consecutive survey to 473,086, the lowest since the record low of 466,252 tallied in the 1986 inventory. Grapefruit acreage fell to a new low of 48,990, representing only 55 percent of the pre-hurricanes figure while Specialty acreage continued to decline to a record low of 19,252.

Total citrus trees are down over 2 percent from 72,164,800 in 2010 to 70,640,700 in 2011. Polk is the new leader with the most trees at nearly 9.9 million, followed closely by Hendry with 9.7 million, DeSoto with 8.4 million, and Highlands with 8.0 million trees. Of the total, oranges comprise over 88 percent; grapefruit, almost 8 percent; and the remainder, including specialty and other citrus, at 4 percent. Since 2010, bearing trees decreased nearly 3 percent to 65,908,700 while non-bearing trees increased by almost 5 percent to 4,732,000.

¹ January freezes in 1971, 1977, 1981, 1982, 1985, and 1986. December freezes in 1983, 1985, and 1989.

² August and September hurricanes in 2004, October hurricane in 2005.

³ One year change beginning in 2009.

All Citrus: Number of Multiblocks (Groves), by Acreage and Survey Year

[A multiblock or grove for this table is a parcel of land, as determined by field personnel. The boundaries of the parcel are easily distinguishable by the field personnel. Within the boundaries is citrus with a homogenous planting scheme]
